Abstract— Past, present and future trends in systems analysis and design were researched that cover the background of the methodologies and technologies used in system development. Their definition and key factors of why they were popular in their respective times were also researched.

Keywords— Waterfall, Object-Oriented Analysis and Design (OOAD), Agile, DevOps, Artificial Intelligence (AI), Internet of Things (IoT).

I. INTRODUCTION

System analysis and design is a process used by many businesses to examine specific company conditions and propose strategies for improving them using more efficient approaches. Companies may utilise this method to remodel their organisation or to achieve corporate growth and profitability goals. System analysis and design often emphasise how systems behave, how they interact with other subsystems, and their ability to achieve a certain purpose. This frequently entails examining a system's performance and the quality of output. Over the years, more and more technologies are being developed to further improve the efficiency of systems analysis and design. With each new technology, it improves the previous approach of system analysis and design while also magnifying its capabilities. This paper will discuss the trends in systems analysis and design throughout time.

II. PAST TRENDS

A. Waterfall Model

The waterfall methodology was first introduced by Winston W. Royce in 1970[1]. It was noted that it was in one of his papers titled "Managing the Development of Large Software Systems". Royce described a software development paradigm using a procedural model with six stages: requirements analysis, design, implementation, verification, integration, and maintenance. By using the waterfall methodology, the goal is set rather early on in to facilitate the work in a goal- and plan-oriented manner [2]. It is organised comprehensively, with tasks, roles, and due dates, from the beginning to the end. The goal is to carry out the original plan as closely as possible. This

offers predictable resources, documented planning, and stability and structure. However, the flaw that comes with the model is that if a task remains undone, the stage cannot proceed [3]. This will cause additional costs than what was planned due to more discussions with the client to clarify their needs. The flaw translates to decreasing trends throughout time as other methodologies are seen to be more viable.

B. Object-Oriented Analysis and Design

Object-oriented analysis and design (OOAD) were first introduced in the 1960s but gained popularity in the late 1990s because it increased developer productivity and software quality [4]. It is a powerful model that works by analysing and collecting user requirements, as well as developing applications using visual aids to improve software [5]. Using OOAD effectively improves software maintenance, reusability, and modifiability. However, the drawback of using this model is that has limited support for functional analysis, mostly because UML representations are limited in large-scale projects [6].

III. PRESENT TRENDS

A. Agile Methodology

Agile methodologies are widely implemented and used around the world. There are over 20 different agile methodologies and their types. Some of them are Scrum, extreme programming, Kanban, lean software development, feature-driven development, agile unified process, and dynamic systems development method (DSDM) [7]. Agile is sometimes described as iterative and incremental, aiming to avoid traditional methodologies that emphasise early design and specification freeze, a fixed project scope, and little customer engagement. Essentially, it is the ability to adapt to changes during product development. This is in contrast with the traditional approach where it is focused more towards the planning instead of the execution. As mentioned, when developing a system with the waterfall methodology, if a phase is not done, then the development cannot proceed. Hence, the agile method became popular because it embraces changes as

changes are inevitable in system development. One of the downsides of this methodology is it heavily revolves around good communication and collaboration between team members and clients [8], [9]. It also often ignores software delivery and deployment [10].

B. DevOps

DevOps was first introduced in 2009, as an integration of development and operations tasks in a team [10]. DevOps' goal is to facilitate collaboration between development and operations, in part by automating tasks for building and deploying code and testing, to reduce software development time, enable continuous software delivery, and increase software stability and thus customer satisfaction [10]. Through the combination of development and operations, it provides flexibility in rapidly changing situations to fulfil the client's requirements. DevOps also shares the same drawback of agile methodology. What sets them apart is DevOps overcomes a weakness of the agile methodology which is the neglect of software delivery and deployment [10].

IV. FUTURE TRENDS

A. Artificial Intelligence (AI) Development

The meaning of Artificial intelligence (AI) is the ability of a digital computer or computer-controlled robot to perform tasks commonly associated with intelligent beings [11]. The term is frequently applied to the project of developing systems endowed with the intellectual processes characteristic of humans, such as the ability to reason, discover meaning, generalize, or learn from experience.

Systems analysis has been transformed due to the power of AI. AI algorithms and machine learning models can now analyse huge volumes of data in a fraction of the time it would take a human analyst [11]. By leveraging advanced analytics techniques, AI can identify patterns, trends, and anomalies that humans might overlook, leading to more accurate and comprehensive analysis.

1) *Enhanced efficiency*: With the ability of AI that can process data with an incredible speed, system analysis now can be completed within a short amount of time. This will allow many users or organizations to identify and able to address issues instantly, improving overall efficiency and reducing the rate of management [11].

2) *Improved accuracy*: AI can eliminate the risk of human error, and can make an analysis more accurate and reliable. By filtering many unnecessary elements from the process, users or organizations can confidently use a conclusion from the data [11].

3) *Data-driven insights*: AI tools can analyse vast amounts of data to provide valuable insights into user behaviour, market trends and design performance. This data-driven approach helps designers make informed decisions [11].

B. Internet of Things (IoT)

The Internet of Things (IoT) is an emerging topic of technical, social, and economic importance. Consumer products, durable goods, cars and trucks, industrial components and facilities, sensors, and other everyday objects are combined with internet connectivity and powerful data analysis capabilities that promise to transform the way we live and work [12].

The power of the Internet of Things involves understanding how different components interact within a complex system. IoT has emerged as a powerful tool in systems analysis, providing a wealth of real-time data that was previously inaccessible. By connecting physical objects to the internet, IoT enables continuous monitoring and analysis of these objects, leading to valuable insights [12].

1) *Real-time data collection*: IoT devices continuously collect data from various sensors and devices embedded within a system. This real-time data allows analysts to gain a comprehensive understanding of the system at any given moment, enabling proactive decision-making [12].

2) *Increased visibility*: IoT provides visibility into previously opaque processes and systems. By monitoring physical objects and collecting relevant data, analysts can identify areas of improvement, optimize operational efficiencies, and enhance overall system performance [12].

3) *Predictive analytics*: With IoT, systems analysts can use powerful predictive analytics algorithms to forecast future trends and events. The ability to anticipate potential issues or predict demand allows organizations to be proactive and respond promptly, minimizing downtime and maximizing productivity [12].

IV. CONCLUSIONS

The version of this template is V2. Most of the formatting instructions in this document have been compiled by Causal Productions from the IEEE LaTeX style files. Causal Productions offers both A4 templates and US Letter templates for LaTeX and Microsoft Word. The LaTeX templates depend on the official IEEEtran.cls and IEEEtran.bst files, whereas the Microsoft Word templates are self-contained.

Causal Productions has used its best efforts to ensure that the templates have the same appearance.

ACKNOWLEDGMENT

The heading of the Acknowledgment section and the References section must not be numbered.

Causal Productions wishes to acknowledge Michael Shell and other contributors for developing and maintaining the IEEE LaTeX style files which have been used in the preparation of

this template. To see the list of contributors, please refer to the top of file IEEETran.cls in the IEEE LaTeX distribution.
